Linear regression

Machine Learning II (2022-2023) UMONS

1 Exercise 1

Consider the hat matrix $H = X(X^TX)^{-1}X^T$, where X is an n by d+1 matrix, and X^TX is invertible.

- (a) Show that H is symmetric.
- (b) Show that H is a projection matrix, i.e. $H^2 = H$. So \hat{y} is the projection of y onto some space. What is the space?
- (c) Show that $H^k = H$ for any positive integer k.
- (d) If I is the identity matrix of size n, show that $(I H)^k = I H$ for any positive integer k.
- (e) Show that trace(H) = d + 1, where the trace is the sum of diagonal elements. [Hint: trace(AB) = trace(BA)]

Consider a noisy target $y = \mathbf{w}^{*T}\mathbf{x} + \epsilon$ for generating the data, where ϵ is a noise term with zero mean and σ^2 variance, independently generated for every example (\mathbf{x}, y) . The expected error of the best possible linear fit to this target is thus σ^2 .

For the data $\mathcal{D} = \{(\mathbf{x}_1, y_1), \dots, (\mathbf{x}_n, y_n)\}$, denote the noise in y_i as ϵ_i and let $\boldsymbol{\epsilon} = [\epsilon_1, \epsilon_2, \dots, \epsilon_n]^T$; assume that $X^T X$ is invertible. By following the steps below, show that the expected in-sample error of linear regression with respect to \mathcal{D} is given by

$$\mathbb{E}_{\mathcal{D}}[E_{in}(\mathbf{w}_{lin})] = \sigma^2 \left(1 - \frac{d+1}{n}\right)$$

- (a) Show that the in-sample estimate of \mathbf{y} is given by $\hat{\mathbf{y}} = X\mathbf{w}^* + H\boldsymbol{\epsilon}$.
- (b) Show that the in-sample error vector $\hat{\mathbf{y}} \mathbf{y}$ can be expressed by a matrix times $\boldsymbol{\epsilon}$. What is the matrix?
- (c) Express $E_{in}(\mathbf{w}_{lin})$ in terms of ϵ using (b), and simplify the expression using Exercise 1(c).
- (d) Prove that $\mathbb{E}_{\mathcal{D}}[E_{in}(\mathbf{w}_{lin})] = \sigma^2 \left(1 \frac{d+1}{n}\right)$ using (c) and their independence of $\epsilon_1, \dots, \epsilon_n$. [**Hint:** The sum of the diagonal elements of a matrix (the trace) will play a role. See Exercise 1(d)]

For the expected out-of-sample error, we take a special case which is easy to analyze. Consider a test data set $\mathcal{D}_{test} = \{(\mathbf{x}_1, y_1'), \dots, (\mathbf{x}_n, y_n')\}$, which shares the same input vector \mathbf{x}_i with \mathcal{D} but with different realization of the noise terms. Denote the noise in y_i' as ϵ_i' and let $\epsilon' = [\epsilon_1', \epsilon_2', \dots, \epsilon_n']^T$. Define $E_{test}(\mathbf{w}_{lin})$ to be the average squared error on \mathcal{D}_{test} .

(e) Prove that
$$\mathbb{E}_{\mathcal{D}, \epsilon'}[E_{test}(\mathbf{w}_{lin})] = \sigma^2 \left(1 + \frac{d+1}{n}\right)$$
.

The special test error E_{test} is a very restricted case of the general out-of-sample error. Some detailed analysis shows that similar results can be obtained for the general case, as shown in Exercise 3.

Consider the linear regression problem setup in Exercise 2, where the data comes from a genuine linear relationship with added noise. The noise for the different data points is assumed to be iid with zero mean and variance σ^2 . Assume that the 2^{nd} moment matrix $\Sigma = \mathbb{E}_{\mathbf{x}}[\mathbf{x}\mathbf{x}^T]$ is non-singular. Follow the steps below to show that, with high probability, the out-of-sample error on average is

$$E_{out}(\mathbf{w}_{lin}) = \sigma^2 \left(1 + \frac{d+1}{n} + o(\frac{1}{n}) \right).$$

(a) For a test point \mathbf{x} , show that the error $y - g(\mathbf{x})$ is

$$\epsilon - \mathbf{x}^T (X^T X)^{-1} X^T \epsilon$$

where ϵ is the noise realization for the test point and ϵ is the vector of noise realizations on the data.

(b) Take the expectation with respect to the test point, i.e., \mathbf{x} and ϵ , to obtain an expression for E_{out} . Show that

$$E_{out} = \sigma^2 + \operatorname{trace}(\Sigma(X^T X)^{-1} X^T \epsilon \epsilon^T X (X^T X)^{-1})$$

[**Hint:** a = trace(a) for any scalar a; trace(AB) = trace(BA); expectation and trace commute.]

- (c) What is $\mathbb{E}_{\epsilon}[\epsilon \epsilon^T]$?
- (d) Take the expectation with respect to ϵ to show that, on average,

$$E_{out} = \sigma^2 + \frac{\sigma^2}{n} \operatorname{trace}(\Sigma(\frac{1}{n}X^TX)^{-1}).$$

Note that $\frac{1}{n}X^TX = \frac{1}{n}\sum_{i=1}^n \mathbf{x}_i\mathbf{x}_i^T$ is an n-sample estimate of Σ . So $\frac{1}{n}X^TX \approx \Sigma$. If $\frac{1}{n}X^TX = \Sigma$, then what is E_{out} on average?

(e) Show that (after taking the expectation over the data noise) with high probability,

$$E_{out} = \sigma^2 (1 + \frac{d+1}{n} + o(\frac{1}{n})).$$

[Hint: By the law of large numbers $\frac{1}{n}X^TX$ converges in probability to Σ , and so by continuity of the inverse at Σ , $(\frac{1}{n}X^TX)^{-1}$ converges in probability to Σ^{-1} .]

In a regression setting, assume the target function is linear, so $f(\mathbf{x}) = \mathbf{x}^T \mathbf{w}^*$, and $\mathbf{y} = Z\mathbf{w}^* + \boldsymbol{\epsilon}$, where the entries in $\boldsymbol{\epsilon}$ are zero mean, iid with variance σ^2 . In this problem derive the bias and variance as follows.

- (a) Show that the average function is $\bar{g}(\mathbf{x}) = f(\mathbf{x})$, no matter what the size of the data set. What is the bias?
- (b) What is the variance? [Hint: Exercise 3]

In the text we derived that the linear regression solution weights must satisfy $X^TX\mathbf{w} = X\mathbf{y}$. If X^TX is not invertible, the solution $\mathbf{w}_{lin} = (X^TX)^{-1}X^T\mathbf{y}$ won't work. In this event, there will be many solutions for \mathbf{w} that minimize E_{in} . Here, you will derive one such solution. Let ρ be the rank of X. Assume that the singular value decomposition (SVD) of X is $X = U\Gamma V^T$, where $U \in \mathbb{R}^{n \times \rho}$ satisfies $U^TU = I_{\rho}$, $V \in \mathbb{R}^{(d+1) \times \rho}$ satisfies $V^TV = I_{\rho}$, and $\Gamma \in \mathbb{R}^{\rho \times \rho}$ is a positive diagonal matrix.

- (a) Show that $\rho < d + 1$.
- (b) Show that $\mathbf{w}_{lin} = V\Gamma^{-1}U^T\mathbf{y}$ satisfies $X^TX\mathbf{w}_{lin} = X^T\mathbf{y}$, hence is a solution.
- (c) Show that for any other solution that satisfies $X^T X \mathbf{w} = X^T \mathbf{y}$, $\| \mathbf{w}_{lin} \| < \| \mathbf{w} \|$. That is, the solution we have constructed is the minimum norm set of weights that minimize E_{in} .
